Angular formarray vs formgroup

The Angular Example FormArray shows how to use the FormArray. The FormArray allows us to add dynamic controls to the reactive forms. In this example, we will take a very simple task to dynamically add/remove skills in an employee form. Applies to: Angular 2 of the last edition of i.e Angular 8. Angular 9, Angular 10, Angular 11What is FormArray Formarray is a way to manage collections of controlling the Angular Form. The controls can be aFormGroup, aFormControl, or another FormArray.We can group Form Controls into Angular forms in two ways. One is using the FormGroup and the other one is FormArray. The difference is how to implement it. The ShapeGroup control becomes a property of the FormGroup. Each control is represented as the key-value pair. While in FormArray, controller becomes part of an arrayBe because it is implemented as Array, it makes it easier to dynamiically add control. Our FormArray Exemplary builds a simple app, which allows us to add the new skills to a dynamic person. Import FormArrayTo use FormArray, first, you need to import the FormArray from the Angular Form Module.import { FormGroup, FormControl, FormArray, FormBuilder } from '@angular/form'Build a Form ModelBuild a form skill template using the FormBuilder. Our form has two fields. the name of the person and his competence. Since the person can have more than one skill, we define skills as FormArray. construction(private fb:FormBuilder) { this.skillsForm = this.fb.group({ skills: this.fb.array([]) , next, a method to acquire skills, which returns the skill fomArray from skills() : FormArray { return this.skillsForm.get(skill) as FormArrayThe Skill FormGroupWe need to take two fields under each skill. Name of the skills & years of export. Therein we create a FormGroup with two fields. The newSkill method creates a new FormGroup and returns it. Note that we will not be able to give a name to group.Dynamically add skillNow form, we need to add a new skill to the FormArray Skills. Since it is an array we can use the push method to add the new skills by using the newSkill method. Note that the newSkill() method returns a FormGroup. The name of the FormGroup is its index in the FormArray. this.skills.push(this.newSkill()) ;D namically removed the SkillUse retireAt method to remove elements from the skills of NanArray.Submit console.log(this.skillsForm.value); ModelNow, it is time to build the model. Use the [fomGroup]=skillsForm to bind the form to the skill model. FomControlName = name list element input name of name property in skillsForm<form[formgroup]=skillsForm(ngsubmit)=onSubmit()><label for=name>Name</label>&l input type=text id=name=name formcontrolname=name><button=submit>Submit</button> Binding FormArray in TemplateWe use the fomArrayName directive to bind the array shape skills to the div element. Now dive there with nothing inside the div tie element ladres yo fom etalaj.<div ></div ></form> ></form> itilize ngFor pou bouk nan chak eleman nan Konpetans FormArray. kite mwen = endeks pral magazen vale endeks la nan etalaj la nan model lokal varyab mwen. Nou pral fe pou sevi ak li yo retire eleman ki soti nan etalaj ladres yo.<div formarrayname=skills><div *ngfor=let skill of skills().controls; let i=index>Chak eleman anba ladres yo se yon FormGroup. Nou pa gen yon non nan FormGroup la. Se Endeks la nan eleman an otomatikman asiyen kom non an pou eleman an. Pakonsekan nou itilize [fomGroupName] = mwen kote mwen se endeks la nan FormArray a mare eleman nan FomGroup nan eleman nan div.<div formarrayname=skills><div *ngfor=let skill of skills().controls; let i=index><div [formgroupname]=i>Finalman, nou ajoute kontwole yo le li sevi avek fomControlName direktif la. <div formarrayname=skills><div *ngfor=let skill of skills().controls; let i=index><div [formgroupname]=i><input type=text formcontrolname=skill><input type=text formcontrolname=exp><button (click)=removeSkill(i)>Retire</button> Epitou, pase endeks la mwen retireSkill<button (click)=removeSkill(i)>Retire</button>Finalman, rele metod la addSkills yo ajoute nouvo ladres. <button type=button (click)=addSkills()>Ajoute</button> That's itAngular FormArray Example App RunningSource Codeapp.component.tsimport { Component, ViewChild, ElementRef } from '@angular/core';import { FormGroup, FormControl,FormArray, FormBuilder } from '@angular/forms' templateUrl: './app.component.html', styleUrls: ['./app.component.css']export class AppComponent { title = 'FormArray Example in Angular Reactive forms'; constructor(private fb:FormBuilder) { this.skillsForm = this.fb.group({ skills: this.fb.array([]) , get skills() : FormArray { return this.skillsForm.get(skills) as FormArray this.skills.push(this.newSkill()); console.log(this.skillsForm.value); constructor(id: string, name: string) {app.component.html<form [formgroup]=skillsForm (ngsubmit)=onSubmit()><label for=name>Non</label><input type=text id=name name=name formcontrolname=name><div formarrayname=skills><div *ngfor=let skill of skills().controls; let i=index><div [formgroupname]=i><input type=text formcontrolname=skill><input type=text formcontrolname=exp><button (click)=removeSkill(i)></button> Retire <button type=submit>Submit</button> <button type=button (click)=addSkills() >Add</button>{sa a.skillsForm.value | json}ReferansSummaryIn Tutorial sa a, nou te aprann ki jan yo kreye yon senp FormArray Egzanp.Ranpli Lis Atik sou Fom Angile FomArray se yon varyant nan FormGroup. Diferans lan kle se ke done li yo vin serialize kom yon etalaj (kom opoze yo te serialize kom yon obje nan ka ta gen FormGroup). Sa a ta ka itil espesyalman le ou pa konnen ki jan anpil kontwol yo pral prezan nan gwoup la, tankou fom dinamik. Kite mwen eseye eksplike pa yon egzanp rapid. Di, ou gen fom kote ou pran lod yon kliyan an pou Pitza. Epi ou mete yon bouton pou kite yo ajoute epi retire</div></div></div></div></form></div></div></div></div></div></div></div></div></div></div></div> retire</div></div></div></div></form></div></div></div></div></div></div></div></div></div> special request. Here is the html element's part: <section><p>Any special request?</p><ul formarrayname=specialRequests><li *ngfor=letter item of orderForm.controls.specialRequests.controls; letter i = index><input type=text formcontrolname={{i}}><button type=button title=Remove Request(click)=onRemoveSpecialRequest(i)>Remove</button ></he> Add<button=button(click)=onAddSpecialRequest()>a request</button></section> and here the class element is defined with special request handling: constructor() { this.orderForm = new FormGroup({ first name: new FormControl('Nancy', Validators.minLength(2)), latestName: new FormControl('Drew'), specialReques: new FormArray([New FormControl(null)]) } } public onSubmitForm() { console.log(this.orderForm.value); } onAddSpecialRequest() { this.orderForm.controls .specialRequests.push(new FormControl(null)); } onRemoveSpecialRequest(index) { this.orderForm.controls[SpecialReque special .retireAt(index); } FormArray offers more flexibility than FormGroup in the sense that it is easier to manipulate FormControls using push, insert and removeAt than using addControl, removeControl, setvalue etc. FormArray methods ensure controls are well followed in the form's hierarchy. hope this helps. While this tutorial contains content that we believe is of great benefit to our community, we are no longer tested or modified to it to ensure you have a error-free learning experience. It's on our list, and we're working on it! You can help us out using report a problem button at the bottom of the tutorial. So you have a form and would like to add dynamical form fields from a response to a user event? It's easy to do with Reactive Shapes and FormArray. FormArray is somewhat like FormGroup and is used in a very similar way, the difference that it uses as an array that is wrapped around an arbitrary amount of FormControl, FormGroup or even other formArray circumstances. With FormArray you can therefore add new form fields or insert into decalatively form fields. Importing FormArray First, on top of importing your other form, you'll want to import FormArray from the Angular modules: app.app.element.tsimport { FormBuilder, FormGroup, FormArray } from '@angular/form'; Now we will initialize our form using FormBuilder in the ngOnInit hook. For this example we'll create a command form that allows the user to add new dynamic items: order FomGroup; article: FormArray; construction(private fomBuilder: FormBuilder) { } ngOniit() { this.orderForm = this.formBuilder.group({ clientName: ', email', ',', items: this.formBuilder.array([this.createm()]) }); } Our article example is a form array instead of a form control, and we're calling a group create method a group creates a form group as the first item in our array. Here's what our created method looks like: create Items(): { return this.formBuilder.group({ name: '', description: ''Price:''}); } Add to the FormArray Now the interesting part is that we can treat our FormArray just like a regular array and push new items into it: add Items(): cancel { this.item = this.orderForm.get('item') as FormArray; this.item.push(this.createm()} } Now it's as simple as calling our addition method in our template when users click to add a new item. FomArray in the Finally pattern, we use the fomArrayName directive in the template bound to array our form: <div formarrayname=items *ngfor=letter item of orderForm.get('items').controls; letter i = index;><div [formgroupname]=i><input formcontrolname=name placeholder=item name><input formcontrolname=description placeholder=Item description><input formcontrolname=priceholder=item></div> Select name: {{orderForm.controls.items.controls[i].controls.name.value}}</div> Notice how our formGroupName's guidelines now take an index instead of a name and we set it up using the index that ngFor gives us. You can also see a way to get to a form control value in the template by crossing our form.
